Abstract

This report reflects how we used Artificial Intelligence (AI) and Machine Learning (ML) in predicting and managing heart disease by detecting it in the earlier phases and treating them accordingly through our vast dataset. Our dataset that is “Heart Disease Dataset”, consists of 1190 rows and 12 columns having both categorical as well as numerical variables.

The process involves Exploratory Data Analysis (EDA) to uncover patterns, detect outliers, and guide us through feature selection. Categorical variables include sex, chest pain type, fasting blood sugar, resting electrocardiographic results, exercise-induced angina, and the slope of the peak exercise ST segment. Numerical variables include age, resting blood pressure, cholesterol level, maximum heart rate, and ST depression induced by exercise.

The main feature on which this study revolves, 'target,' which is a categorical variable that shows having or not having heart disease. Data collection procedures prioritize informed consent, ethical guidelines, standard protocols, and data quality assurance. Further studies might involve data from patient medical histories, health surveys, smart devices, and electrocardiogram data.

EDA process involves loading data, understanding its structure, generating summary statistics, creating visualizations, handling missing data, detecting outliers, performing feature engineering, exploring correlations, normalizing variables, and interactive exploration. Research indicates that ECG results, rather than initially presumed factors like cholesterol and age, play a significant role in heart disease prediction.

Despite having a dataset with limited size, the approach we used enables the implementation of various machine learning models. This document also concludes that a classification algorithm is most suitable for further analysis.

Introduction

Heart disease includes the conditions that affect the heart, heart failure, including coronary artery disease, and arrhythmias. Common symptoms include pain in the chest or shortness of breath, discomfort, fatigue, and irregular heartbeats. Some risk factors include high blood pressure, high cholesterol, smoking, obesity, and a sedentary lifestyle.

Various ways in which we can help prevent heart disease such as a healthy lifestyle, including regular exercise, monitoring blood pressure, a balanced diet, and avoiding tobacco. Regular health check-ups and cholesterol levels, and staying hydrated are crucial. Additionally, minimizing processed food consumption and being aware of family history can help in preventing heart disease. Early detection and management are crucial for minimizing complications and improving heart health.

Artificial Intelligence and Machine Learning play a pivotal role in predicting and managing heart disease. These technologies analyze vast datasets, enabling early detection through predictive modeling based on patient information. AI-powered tools aid in interpreting medical imaging, enhancing diagnostic accuracy. ML algorithms can assess individual risk factors, providing personalized treatment plans for better outcomes. Integrating AI and ML into healthcare systems empowers clinicians with valuable insights, facilitating proactive interventions and ultimately improving cardiovascular care.

The large dataset for heart disease contains many outliers and missing values therefore before feeding that to the model, the uncovering of patterns, detecting of outliers, and guiding the selection of relevant features is done. It assists in cleaning and visualizing data, ensuring accuracy, and highlighting key relationships between risk factors. EDA is integral in refining datasets and enhancing the effectiveness of predictive models for improved cardiovascular risk assessment.

Methods

Exploratory Data Analysis

Exploratory Data Analysis (EDA) is a statistical approach to analyzing and visualizing data sets to summarize their main characteristics, often with the help of graphical representations. It involves identifying patterns, trends, outliers, and relationships within the data to gain insights into its underlying structure. EDA is a crucial preliminary step in the data analysis process, helping researchers and data scientists understand the data, clean it, and inform subsequent modeling or analysis decisions.

Dataset Details

The data set we chose is the "Heart Disease Dataset".

This dataset consists of 1190 rows and 12 columns. This dataset gives us a brief overview of the number of male and female suffering from heart disease due to various factors. It consists of both numerical and categorical values.

CATEGORICAL VARIABLES –

	Variable Name	Description	Type of variable
1	sex	0 = male 1 = female	Categorical
2	chest pain type	1 = typical angina 2 = atypical angina 3 = non-anginal pain 4 = asymptomatic	Categorical
3	fasting blood sugar	condition = (> 120 mg/dl) 1 = True 0 = False	Categorical
4	resting ecg	resting electrocardiographic results 0 = normal 1 = having ST-T wave abnormality 2 = showing probable or definitive left ventricular hypertrophy	Categorical
5	Exercise angina	exercise induced angina. 1 = yes	Categorical

		0 = no	
6	ST slope	the slope of the peak exercise ST segment 1 = unsloping 2 = flat 3 = down sloping	Categorical

NUMERICAL VARIABLES –

	Variable Name	Description	Type of variable
1	age	Age of the patient	Numerical
2	resting bp s	resting blood pressure (mm Hg)	Numerical
3	cholesterol	the cholesterol level in blood (mg/dl)	Numerical
4	max heart rate	maximum heart rate reached (Bpm)	Numerical
5	old peak	ST depression induced by exercise relative to rest (mV)	Numerical

Main Study Variable

The main study variable of our dataset is 'target', which research, and categories whether the person has heart disease or not. Therefore, it is a categorical variable, usually working on two main categories namely, patient have heart disease and patient does not have heart disease.

Data collection instruments and procedures

To acquire data from these sources, the following methodologies can be employed:

- Securing informed consent from participants
- Adhering to ethical guidelines
- Implementing standard protocols for data collection
- Ensuring data quality through quality assurance measures
- Conducting follow-up assessments of patient data

For future, more comprehensive investigations, data can be gathered from diverse outlets, including:

- Patient medical histories
- Health surveys

- Smart devices like smartwatches
- Electrocardiogram data

Exploratory Data Analysis

Step by step process

Exploratory Data Analysis (EDA) typically involves the following steps:

1. **Load Data:**
    a. Import the dataset into a data analysis tool or programming environment such as Python (using libraries like Pandas) or R.
2. **Understand the Data:**
    a. Check the first few rows of the dataset to understand its structure.
    b. Inspect column names, data types, and any missing values.
3. **Summary Statistics:**
    a. Generate descriptive statistics (mean, median, standard deviation) to understand the central tendency and variability of the data.
4. **Data Visualization:**
    a. Create visualizations such as histograms, box plots, and scatter plots to explore the distribution and relationships between variables.
    b. Use seaborn, matplotlib (in Python), or ggplot2 (in R) for visualization.
5. **Handle Missing Data:**
    a. Identify and handle missing values through imputation or removal, depending on the extent of missing data and the nature of the analysis.
6. **Outlier Detection:**
    a. Visualize and identify outliers that may skew the analysis or modeling. Decide whether to keep, transform, or remove outliers based on the context.
7. **Feature Engineering:**
    a. Create new features or transform existing ones to extract more meaningful information for analysis.
8. **Correlation Analysis:**
    a. Explore correlations between variables to identify potential multicollinearity or relationships that may impact the analysis.
9. **Data Transformation:**
    a. Normalize or standardize variables as needed, especially when using algorithms sensitive to scale.
10. **Interactive Exploration:**
    a. Utilize interactive tools or dashboards for dynamic exploration of the data, enabling a deeper understanding of patterns and trends.
11. **Document Findings:**
    a. Summarize key observations, patterns, and potential insights obtained during the EDA process.

These steps provide a comprehensive approach to exploring and understanding a dataset, setting the stage for more advanced analytics or machine learning tasks. The specific techniques and tools used may vary based on the data and the goals of the analysis.

Results

Even though not having a large amount of data as comparable in today's world, it has allowed us to create a simple model and then use various machine learning ability tools and techniques to peek inside. At the start, we hypothesized, using researched domain knowledge, that factors such as cholesterol and age would be major factors in the model. This dataset did not show that.

Instead, the number of major factors and aspects of ECG results dominated. We feel like we have learnt a thing or two about heart disease, which will help us in future to open our books of knowledge instead of finding for the existing ones while analyzing for a similar dataset/field/sector.

In our opinion, this sort of approach will become increasingly important as machine learning has a greater and greater role in health care.

Conclusions and Future Work

After the heart disease dataset was explored and largely analyzed that included outlier detection and working on each feature of the dataset.

We concluded that the most suitable algorithm for further analysis will be classification.
